Food Remedy API
Competitive App Research: IntolerAPP [RE023]

Prepared For: Food Remedy API
Team Author: Zhi Wang
Date: 3 August 2025 (T2 2025)

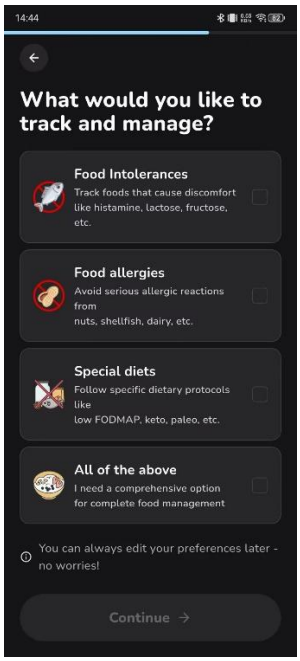
INTRODUCTION

IntolerAPP is a specialised nutrition tracking application designed to support individuals with food intolerances by helping them identify and avoid ingredients that may trigger adverse reactions. Unlike general nutrition apps, IntolerAPP focuses specifically on food components such as FODMAPs, histamines, and other common intolerance-related compounds. The app offers a filtering mechanism that allows users to personalise their dietary restrictions and scan or search food items to assess their compatibility.

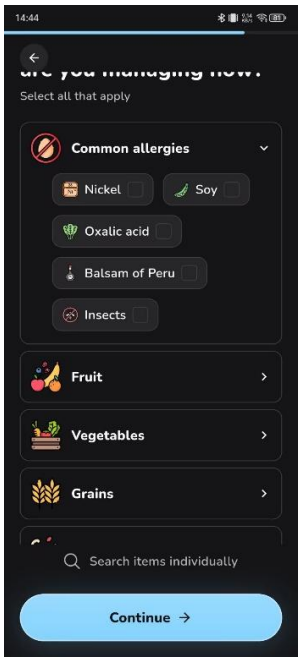
This competitive research evaluates how IntolerAPP communicates ingredient risk, structures its user experience for those with dietary sensitivities, and facilitates informed decision-making. It also considers how the app's approach to filtering and intolerance profiling could be adapted or integrated into the Food Remedy API platform to broaden its utility for sensitive users. The goal is to extract functional and design insights that can contribute to more inclusive and medically-aware food recommendation systems.

FILTERING MECHANISM FOR FOOD INTOLERANCES

At the core of IntolerAPP lies its dynamic filtering system, which empowers users to exclude food items based on specific intolerance triggers. Upon launching the app, users can configure their personal intolerance profile by selecting from a range of dietary sensitivities, including but not limited to FODMAPs, histamines, lactose, gluten, and fructose. This initial setup ensures that every subsequent search or scan is automatically filtered through the user's chosen dietary restrictions.



The food filtering process is designed to be intuitive and immediate. When users search for or scan a product, IntolerAPP highlights ingredients of concern using a traffic-light style indicator—green for safe, orange for moderate caution, and red for high risk. Each ingredient is annotated with contextual information explaining why it may cause discomfort, enabling users to better understand the relationship between symptoms and food components.



The app categorises ingredients into predefined groups (e.g., high-fructose fruits, fermented foods high in histamine) and allows for additional manual toggling. This offers both a systematic and personalised assessment, helping users avoid harmful ingredients without needing to read lengthy nutritional labels. The filtering logic appears to draw from established medical and dietary guidelines, such as Monash University's FODMAP classification and general histamine response research.

IntolerAPP's filtering approach not only protects users from potential reactions but also acts as an educational tool by gradually building awareness about problematic food categories. The combination of visual cues, detailed ingredient explanations, and flexible user control enhances the app's accessibility for a broad spectrum of intolerance-related needs.

PERSONALISATION AND USER CONFIGURATION

One of IntolerAPP's most distinguishing features is its focus on personalisation through detailed user configuration. From the moment a user begins onboarding, the app prompts them to specify their dietary restrictions by selecting from a list of common intolerances such as lactose, fructose, gluten, sulfites, histamines, and multiple FODMAP subtypes. This profile becomes the foundation of all in-app food filtering and recommendations.

The configuration process is both user-friendly and medically informed. Users can toggle intolerance types on or off at any time, allowing the app to dynamically adjust its scanning and database responses. For example, if a user enables "histamine intolerance" and disables "gluten sensitivity," the app prioritises highlighting histamine-rich foods while ignoring gluten warnings. This level of control ensures that users receive only the most relevant warnings for their personal health conditions.

In addition to ingredient-level filtering, IntolerAPP supports personal tracking through a built-in symptom diary. This feature enables users to log how they feel after consuming specific items, creating a feedback loop between dietary behaviour and physiological response. Over time, the app can use this data to refine its alerts and recommendations, further aligning its suggestions with individual needs.

Users are also able to customise notification preferences, language settings, and severity thresholds for certain ingredients. These adjustments offer flexibility for different use cases—for example, someone with mild lactose sensitivity may still wish to consume low-lactose foods, while someone with a severe reaction may need stricter warnings.

The strength of IntolerAPP's personalisation model lies in its modularity and responsiveness. Rather than imposing a static dietary filter, it adapts to each user's needs and evolves with their dietary experience. This makes it particularly well-suited for users with multiple overlapping sensitivities or those exploring possible intolerance causes over time.

INSIGHTS FOR FOOD REMEDY API

The functionality and user experience design of IntolerAPP offer several key insights that could inform future enhancements to the Food Remedy API platform. While both applications focus on helping users make informed food choices, IntolerAPP goes further in addressing individual dietary sensitivities through advanced filtering and personalisation. This difference highlights opportunities for Food Remedy to expand its scope beyond general nutrition and into targeted intolerance support.

Currently, Food Remedy's features revolve around ingredient transparency, basic nutritional evaluation, and health-tag-based search. However, it lacks an embedded

system for managing food intolerances through dynamic user profiles. By contrast, IntolerAPP allows users to configure specific intolerance filters and provides clear visual warnings tied to personal health preferences. Incorporating a similar filter-driven system in Food Remedy could significantly increase its usability for users with conditions like IBS, lactose intolerance, or histamine sensitivity.

Another notable distinction is IntolerAPP's focus on contextual education. Instead of simply flagging foods as "unsafe," the app explains the underlying triggers and symptom associations. This transforms the app into not only a tool for avoidance but also one for learning. Food Remedy could benefit from adding brief, digestible explanations beside flagged ingredients, helping users understand the rationale behind recommendations.

Furthermore, IntolerAPP's integration of a symptom diary introduces a feedback loop that supports more adaptive and personalised results over time. This concept aligns well with Food Remedy's goal of becoming a more intelligent dietary assistant. While Food Remedy currently relies on static food data, the inclusion of a personal tracking element could enable the system to generate dynamic suggestions based on user feedback and history.

Lastly, IntolerAPP's modular filter design makes it scalable for additional intolerance types or evolving dietary science. Food Remedy, if equipped with a similarly flexible backend, could adapt to future use cases such as cultural dietary exclusions, rare sensitivities, or emerging health trends.

These observations suggest that while Food Remedy offers a strong foundation in general food evaluation, integrating advanced filtering, contextual education, and user-specific adaptation—as demonstrated by IntolerAPP—could significantly elevate its value and appeal to a broader, health-sensitive audience.

RECOMMENDATIONS FOR INTEGRATION

Based on the functional strengths and user-oriented design of IntolerAPP, several actionable recommendations emerge for enhancing the Food Remedy API platform. These suggestions aim to improve personalisation, health relevance, and long-term user engagement:

1. **Introduce Intolerance-Based Filtering Tags**
   Develop a tagging system that associates food items with intolerance risk categories such as "High FODMAP," "Histamine-Rich," or "Lactose-Containing." Each tag should be linked to a risk level and integrated with the user's profile settings, allowing the app to filter and prioritise content accordingly.
2. **Enable Configurable Intolerance Profiles**
   Allow users to build personal intolerance profiles during onboarding or in settings. These profiles should be editable and affect both search results and warnings. Flexibility should be given for users to manage multiple sensitivities simultaneously.
3. **Implement Ingredient-Level Warning Indicators**
   Display visual cues (e.g., green/yellow/red icons) beside ingredients that align with the user's profile, mimicking IntolerAPP's traffic-light system. These

indicators should be context-aware, adjusting based on user severity settings.

4. **Add Contextual Explanations for Trigger Ingredients**
   Alongside flagged ingredients, provide concise educational content explaining why the ingredient may pose a risk (e.g., “High in histamine – may cause skin flushing or headaches”). This helps users understand the science behind the app’s decisions and encourages health literacy.
5. **Consider Adding a Symptom Tracking Diary**
   Incorporate a lightweight logging feature where users can record post-meal symptoms. Over time, the system could learn patterns and provide better recommendations. Data privacy should be respected, with optional opt-in functionality.
6. **Design for Future Scalability and Specialised Filters**
   Ensure the app’s filtering logic is modular and extensible. This will allow easy integration of additional filters in the future (e.g., sulfite sensitivity, low oxalate diets), keeping the platform adaptable to evolving dietary science and user needs.

CONCLUSION

IntolerAPP demonstrates how personalised filtering, medical awareness, and intuitive design can converge to address the needs of individuals with food intolerances. Through its modular intolerance profiles, real-time ingredient risk indicators, and educational support, the app empowers users to make informed dietary decisions tailored to their specific health sensitivities.

This research highlights a clear opportunity for the Food Remedy API platform to evolve from a general nutrition information service into a more adaptive and user-centric dietary assistant. By incorporating key features such as configurable intolerance filters, visual ingredient warnings, and contextual guidance, Food Remedy can expand its utility to users managing conditions like IBS, histamine sensitivity, or lactose intolerance.

Moreover, adopting IntolerAPP’s design philosophy of transparency, simplicity, and user empowerment aligns closely with modern health tech expectations. With a scalable filtering framework and optional symptom tracking, Food Remedy has the potential to serve not only as a food evaluation tool but as a long-term wellness companion.

As the demand for personalised dietary tools continues to rise, integrating these advanced intolerance-aware features will not only improve engagement and trust but also distinguish Food Remedy as a forward-thinking platform in the health and nutrition landscape.
