

RE012 – Food Remedy Closed Beta Survey Distribution and Findings

Summary

The Food Remedy closed beta survey was distributed to team members to evaluate the current application before further development and wider release. A total of 7 responses were collected. Overall, testers considered the application functional and identified useful features such as product details, barcode scanning, user preferences and recommendations. However, the results also identified several issues that should be addressed before public release, particularly allergen detection, product database coverage, recommendation accuracy, navigation, accessibility behavior and existing software bugs.

The overall satisfaction rating was 2.57/5, while only 3 of 7 respondents (43%) said they would recommend the application. Two respondents selected "No" and two selected "Maybe". This indicates that the current version provides a useful foundation but requires further refinement before it is ready for wider deployment.

Survey Findings

Usability and Application Experience

Login was generally acceptable, with 3 respondents rating it Easy and 4 Neutral. Navigation received an average rating of 3.57/5, indicating a reasonably usable experience, although individual testers reported navigation glitches and difficulty returning to previous screens.

The overall design and layout received an average rating of 3.14/5. This suggests that the interface is functional but could be improved in consistency, accessibility and visual presentation.

Feature Usefulness

The Barcode Scanner received an average rating of 3.57/5, showing that users see value in the feature. Product Details received a lower average rating of 2.86/5, although it was selected as the most useful feature by 4 respondents. This suggests that the underlying product information is highly valuable, but the quality and completeness of the information need improvement.

Personalized Food Recommendations received an average rating of 3.00/5, while Shopping Cart and Checkout received 2.86/5. The results therefore show that the main application concepts are useful, but some of the supporting functionality is not yet sufficiently reliable.

Bugs and Functional Issues

Most respondents **did not experience an application crash**: 6 of 7 respondents reported no crashes, while one reported a crash. Similarly, 6 respondents reported no performance issues, with only one reporting slow loading, freezing or lag.

However, the open-ended responses identified several functional problems:

- Product information is sometimes missing even when a product is displayed.
- Some grocery products cannot be scanned because of limited database coverage.
- Allergen detection does not always provide accurate information.
- Navigation has glitches, including difficulty going back.
- Some users experienced SQLite/console errors.
- Profile photo upload was reported as unsuccessful.
- The accessibility feature was reported to read text without prompting.
- Recommendation results are not always accurate.

These findings are particularly important because previous research identified dietary restrictions, allergen classification and product-detail information as core parts of the Food Remedy system.

Recommendation System

The recommendation system received mixed feedback. 4 of 7 respondents (57%) said that recommended products were "Mostly" relevant to their dietary preferences, while 3 selected "Sometimes". No respondents selected "Always".

Testers specifically requested improved preference accuracy and allergen handling. One response suggested that products containing a user's allergens should receive a 0% recommendation, while suitable products should receive higher recommendation percentages.

This is consistent with historical research, which identifies personalization based on user goals and dietary preferences as directly relevant to the current recommendation workflow.

Positive Feedback

Despite the issues identified, testers recognized several strengths in the current application. The most appreciated features were:

- Product details and nutritional information.
- Barcode scanning.
- User preferences and recommendations.
- Shopping Cart functionality.
- The overall concept of helping users understand the nutritional suitability of food products.

One tester noted that the existing application provides a strong basic structure and could become useful for everyday dietary decision-making after further improvements.

Key Recommendations

Based on the survey responses, the following priorities are recommended for the next development cycle:

1. **Improve the product database** so that commonly purchased grocery products can be recognized through barcode scanning and display complete product information.
2. **Fix allergen detection and dietary classification** to ensure products containing relevant allergens are correctly identified and reflected in recommendations.
3. **Improve recommendation accuracy** by ensuring user preferences and dietary requirements directly influence recommendation scores.
4. **Fix existing bugs** affecting navigation, profile photo uploads, SQLite errors, product information and accessibility behavior.
5. **Improve navigation and UI usability**, particularly the back-navigation experience and accessibility control placement.
6. **Improve Product Details**, ensuring nutrition, ingredients and allergen information is complete and reliable.
7. **Improve the recommendation interface**, potentially providing a dedicated page where users can easily discover suitable products.
8. **prioritize reliability over adding large numbers of new features** before public release.

These priorities also align with previous research recommending continued application of dietary-restriction and allergen research within the product data pipeline and improvements to performance and deployment readiness.

Conclusion

The closed beta survey indicates that Food Remedy **has a useful foundation**, with testers recognizing value in product information, barcode scanning, personalization and the overall concept. **However, the 2.57/5 overall satisfaction score and 43% recommendation rate** demonstrate that further development is required before public release.

The most important next step should be to fix existing functional problems and improve the reliability of the underlying product and allergen data, rather than prioritizing additional features. **Improving allergen detection, product coverage, recommendation accuracy, navigation and accessibility** should form the next batch of work. Addressing these areas

will provide a more reliable user experience and support the project's longer-term goal of improving recommendation quality and production readiness.
